27. September 2023

Data collection No data have been collected for this study yet.

Hypothesis

- Photosynthetic capacity decreases with latitude but never reaches zero since other factors besides climate impact the current northern limit of yellow birch.
- With increasing latitude, yellow birch individuals allocate relatively higher fractions of their produced carbohydrates for growth, leaving less for other functions such as reproduction because the environmental conditions become gradually less suited for photosynthesis when moving northward.

Data collection procedures At each plot, photosynthetic gas exchange measurements will be carried out for 5 different yellow birch saplings and adults (dbh = 1-9 cm), using the LI-6800 Portable Photosynthesis System (Li-Cor Inc., Lincoln, NE, USA) with the RACiR method (Stinziano et al., 2017). Measurements will be carried out in a closed chamber to control for weather conditions such as temperature (aiming for 25 °C, Dally-Bélanger & Girard, 2022) and air moisture content. To complement the RACiR measurements and make comparisons between leaves easier (e.g. through NDVI), a field spectroradiometer (PSR-3500 Spectral Evolution Inc.) will be used to measure the spectral properties of each sampled leaf. Next, the diameter at breast height of each sampled tree will be measured and a core sample taken to determine the radial growth rate. All trees in the plot will be mapped and the plot canopy openness measured using a LAI-2200C Plant Canopy Analyzer (Li-Cor Inc., Lincoln, NE, USA). A soil sample will be taken that will be analysed in the lab to consider any soil variability.

Every site will be visited throughout the summer of 2024. All $V_{c,max}$ and J_{max} measurements will be taken in a short period of time at the end of summer to ensure leaf maturity. Weather conditions will be controlled for as much as possible, aiming for clear skies 5 days before and during measurements.

Analyses The obtained A-Ci curves will be corrected by the plot's baseline curves (based on measurements in an empty chamber, Stinziano et al., 2017). Next, all individual, corrected, curves will be fit in order to extract the values for $V_{c,max}$ and J_{max} (Dally-Bélanger & Girard, 2022). This is straightforward when using the plantecophys package (Duursma, 2015), 16 developed for the R environment (R Core Team, 2022). The other relevant parameters to estimate CO₂ assimilation rates (mesophyll conductance g_m , dark respiration R_d and photorespiratory compensation point Γ^*) typically show little phenotypic variation and can be derived from literature (Farquhar et al., 1980). Tree ring width will be prepared and measured using standard methods (Swetnam et al., 1985) and subsequently converted to basal area increments using the tree diameter.

In case of data normality, a multi-way ANOVA test (and possibly Tukey tests, Abdi & Williams, 2010) will be carried out to assess the significance of latitude on $V_{c,max}$ and J_{max} . Contrasting ratios of $V_{c,max}$ (or J_{max}) and basal area increments with

latitude will allow to determine the different carbon allocation strategies of yellow birch over its range in Quebec. Lastly, the derived J_{\max} and $V_{c,\max}$ values will be used to model photosynthesis capacity for sampled individuals under future climatic conditions (e.g. temperature, VPD, atmospheric CO₂), to corroborate the projections in my third study using the Photosyn function of the plantecophys package.

Outliers and exclusions	<p>Individuals that yield $V_{c,\max}$ and/or J_{\max} values that lie outside the reported values in literature by more than 2σ will be discarded.</p> <p>Subjects missing data will be included until they miss so much the fitting is no longer acceptable</p>
Sample size	<p>75 adult and 75 juvenile individuals (5 sites x 3 plots/site x 5 individuals/plot).</p> <p>This design allowed to maximise the sample size with the available time and funds.</p>
Study type	Field Survey
